

This OpenSees model is a 3-story, 3-bay steel special moment resisting frame, which is run for different ground motion records. This model has been designed by SAC/FEMA-355-C and the details can be found in appendix B of the FEMA 355-C. The number of ground motions may vary from 1 up to 44 depends on what number the user chooses.

Following figure shows the sketch of the geometric details of the finite element model.

The outputs of this finite element model are the dynamic responses of the structure with respect to each of the earthquake ground motion records. The outputs are top displacements and also base shears which are recorded in the corresponding folder with respect to each earthquake.

Please make sure that when you download the model to your desktop computer, the files and folders are assembled based on the following data structure. It is noted that the capital and lower letters should be exactly same as the following figure.

As illustrated in the following figure, the output results are saved at a folder called “UnprocessedOutput” after running the model. This folder is located at the major “SAC_FEMA355C_3Story_SMRF” folder.
